Abstract

Based on existing software testability models for object oriented software, we have proposed a new testability assessment model for object oriented software. The model is based on those six important internal programming features of object oriented design which are not used before together at the same time in spite of being highlighted in some or other research. These factors are assessed using popular static object oriented metrics and their link with testability is established. The model is further analysed using Multi Criteria Decision Making (MCDM) approach. The model would be validated using Analytic Hierarchy Process (AHP). The proposed model and evaluation technique helps software engineering practitioners to choose the best alternative amongst available options by analysing the Testability.

Keywords: Software Testability Assessment Model, Object Oriented Testability, Static Metric, AHP.

1. Introduction

Testability is one of the qualitative factors of software engineering which has been accepted in McCall and Boehm software quality model, which built the foundation of ISO 9126 software quality model. Formally, Software testability has been defined and described in literature from different point of views IEEE [1] defines it as “The degree to which a system or component facilitates the establishment of test criteria and performance of tests to determine whether those criteria have been met” and ISO [2] has defined software testability as functionality or “attributes of software that bear on the effort needed to validate the software product”.

The testability research actually is done from the prospect of reducing testing effort and testing cost which is more than 40% of total development cost of any software [3]. Still, the research in the field of testability has not been done in much detail. As discussed in our previous work about testability and testability metrics [4], [5], it has been found that testability research has taken a speed up in past few years only. Tough, much of the work has been done using various object oriented featured metrics only. In this paper we have proposed a testability model for assessment during design time and evaluated the same using AHP technique.

This paper is organized as follows: Section2 gives brief overview of software testability related work. Section3 showcases the proposed testability assessment model from design perspective. Section4 provides overview of material and methodology used during this research. Section5 presents the details of testability evaluation based on proposed model using AHP. It is followed by result and findings in section with conclusion drawn in section 7.

2. Related Work

2.1 Software Testability

Software testability measurement refers to the activities and methods that study, analyze, and measure software testability during a software product life cycle. Unlike software testing, the major objective of software testability measurement is to find out which software components are poor in quality, and where faults can hide from software testing. Now these measurements can be applied at various phases during software development life cycle of a system. In past number of research efforts were made addressing software testability measurement. The focus of past studies was on how to measure software testability at various software development phases like Design Phase [6]–[13] and Coding Phase[14]–[17]. Lot of stress has been given upon usage of object oriented metrics for object oriented software testability evaluation during these researches. The metrics investigated related to object oriented software testability assessment mostly belong to static software metrics category. These metrics were mostly adapted from CK, MOOD, Brian, Henderson-Sellers metric suite [18]–[21]. Furthermore, Lot of empirical studies has been done in showing the correlation of these metrics with unit testing effort [22]–[25]. Also found that few studies have been focussed on UML diagram features from software testability improvisation prospect during review of these design diagrams [26]–[29]. All this work has been explained in depth in our previous research work [4],[5]. But still very less work has been found in testability analysis using MCDM techniques, in
spite of the fact that the testability factor depends on multiple criteria which is explained next.

2.2 Analytical Hierarchy Process

In context with software engineering problems, very few studies related to multi-criteria decision making (MCDM) approach has been done and published. Saaty [30] proposed AHP as one of the most practical method based on MCDM. There are other popular methods such as Fuzzy-AHP and preference ranking organization method of enrichment evaluations (PROMETHEE-2), all capable of solving logistics as well as technical systems. Now, when it comes to testability very less of it is validated ever using any MCDM techniques.

AHP technique is proposed by Saaty, which based on pair-wise matrix to determine indistinctiveness in MCDM problems. It helps in decision making on the basis of needs and understanding of the problem [30]. P. Khanna [31] have proposed primitive work in this field using AHP for testability which is not supported by any empirical study on the data. Dubey et. al. [32] have done study on object oriented usability. Though some work have been found for aspect oriented software testability and reusability assessment using MCDM technique done by Singh and Sangawan [33], [34], which has been technically found useful in how technique done by Singh and Sangawan [33], [34], [35], [36], [37].

These six object oriented features play a very significant role in testability improvisation directly or indirectly. This relation has been build based on thorough study of publications [2], [20], [35], [38], [39] etc.

<table>
<thead>
<tr>
<th>OO Feature</th>
<th>Testability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Encapsulation</td>
<td>It is defined as a kind of abstraction that enforces a clean separation between the external interface of an object and its internal implementation</td>
</tr>
<tr>
<td>Inheritance</td>
<td>It is a measure of the ‘is-a’ relationship between classes.</td>
</tr>
<tr>
<td>Coupling</td>
<td>It is defined as the interdependency of an object on other objects in a design.</td>
</tr>
<tr>
<td>Cohesion</td>
<td>It defines as the internal consistency within the parts of design.</td>
</tr>
<tr>
<td>Size &amp; Complexity</td>
<td>It’s the measure of size of the system in terms attributes or methods included in the class and capture the complexity of the class.</td>
</tr>
<tr>
<td>Polymorphism</td>
<td>Polymorphism allows the implementation of a given operation to be dependent on the object that “contains” the operation.</td>
</tr>
</tbody>
</table>

The studies indicate encapsulation promotes efficiency and complexity. Inheritance has a significant influence on the efficiency, complexity, reusability and testability or maintainability. While low coupling is considered good for understandability, complexity, reusability and testability or maintainability, whereas higher measures of coupling are viewed to adversely influence these quality attributes. Cohesion is viewed to have a significant effect on a design’s understandability and reusability. Size & Complexity has a significant impact on understandability, and testability or maintainability. Polymorphism reduces complexity and improves reusability. Though these features can be measured by many metrics options available as discussed earlier [5]. Most of these metrics are accepted by practitioners on ‘heavy usages and popularity’ and by academic experts on empirical (post
development) validation. But to keep study simple from AHP evaluation aspect we have chosen the few basic but popular metrics amongst testability researchers.

So, the proposed testability assessment model with respect to internal design features using static metrics is as shown in Fig1. It is based on six above mentioned object oriented features from testability perspective as pointed in Binders research too [6]. Out of all the popular metrics suites discussed in our previous work [41] six of these static metrics as explained below in Table2 have been identified for the evaluation of each of these feature and their effects on any object oriented software testability at design time.

![Fig 1: Proposed Software Testability Assessment Model with Static Metrics](image)

As described in Table2 below for Encapsulation evaluation number of methods metrics (NOM) is being chosen by many researchers for the effect of information hiding on testability [10], [38]. So we kept it for encapsulation evaluation for our model too. Inheritance is evaluated using Number of Children metrics (NOC), one of the most popular and efficient inheritance metrics [22], [36], [41], [42]. For Coupling we chose coupling between objects (CBO) and for Cohesion we opted cohesion metrics (Li & Henry version) (LCOM). These two were the most sought after and unparalleled metrics available for assessing coupling and cohesion effect on testability as per literature study and popularity amongst industry practitioners [10], [20], [22], [24], [37], [43]. Though Size & Complexity can be easily measured by other metrics in this category but we chose weighted method complexity (WMC) metrics due to its significant role and association in number of test case indication pointed [6], [22], [42]. Polymorphism is one of the underlying factors affecting testability but as quite stressed by early researchers like Binder and others [6], [45] as it results in testability reduction we chose polymorphism factor metrics (POF/PF) for testability assessment.

<table>
<thead>
<tr>
<th>Testability Factor</th>
<th>Metrics Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Encapsulation</td>
<td>No of Method (NOM)</td>
<td>This metric is the count of all the methods</td>
</tr>
<tr>
<td>Inheritance</td>
<td>No of Children (NOC)</td>
<td>This metric is the count of children of super-class in the design.</td>
</tr>
<tr>
<td>Coupling</td>
<td>Coupling Between Object (CBO)</td>
<td>This metric count of the different number of other classes that a class is directly coupled to. (Two classes are coupled when methods declared in one class use methods or instance variables defined by the other class)</td>
</tr>
<tr>
<td>Cohesion</td>
<td>Cohesion Metric (LCOM)</td>
<td>This metric computes the relatedness among methods of a class based upon the parameter list of the methods.</td>
</tr>
<tr>
<td>Size &amp; Complexity</td>
<td>Weighted Method Complexity (WMC)</td>
<td>It is the count of sum of all methods complexities in a class</td>
</tr>

<td>Polymorphism</td>
<td>No of Methods overridden (NMO)</td>
<td>It is count of overridden method in a subclass</td>
</tr>
</tbody>
</table>

4. Material And Methodology

4.1 AHP Methodology

It initially requires the goal objective to be divided in to hierarchy of factors and sub-factors, which can be easily analysed individually. Once the hierarchy is build the decision maker’s job is to evaluate the problem as follows:

**Step1. Reciprocal Matrix Formation:** First, a pair-wise comparison matrix has been constructed based on the factors. Every factor needs to compare with the immediate next factor. A common scale by Saaty as shown in Table3 below is used for the same.

The matrix thus formed somewhat look likes this, Suppose for n number of factors, F₁, F₂,...,Fₙ are considered, which are to be compared. Relative weight of Fᵢ relating to Fⱼ denoted as mᵢⱼ and a...
A square matrix $A = [m_{ij}]$ of order $n$ will be formed as given in equation (1) below.

$$A = \begin{bmatrix} F_1 & F_1 & \cdots & F_1 \\ 1 & m_{12} & \cdots & m_{1n} \\ F_2 & 1/m_{12} & \cdots & 1/m_{12} \\ \vdots & \vdots & \ddots & \vdots \\ 1/m_{1n} & 1/m_{2n} & \cdots & 1 \end{bmatrix}$$

(1)

Here, $m_{ij} = 1/m_{ji}$ and $i$ does not equal to $j$ and $m_{ii} = 1$ for all $i$. Hence the calculated matrix is known as reciprocal matrix.

### Table 3: Satty Rating Scale [30]

<table>
<thead>
<tr>
<th>Intensity of Importance</th>
<th>Definition</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Equal Importance</td>
<td>Elements $C_i$ and $C_j$ are equally important</td>
</tr>
<tr>
<td>3</td>
<td>Weak Importance of $C_i$ over $C_j$</td>
<td>Experience and Judgment slightly favor $C_i$ over $C_j$</td>
</tr>
<tr>
<td>5</td>
<td>Essential or Strong Importance</td>
<td>Experience and Judgment strongly favor $C_i$ over $C_j$</td>
</tr>
<tr>
<td>7</td>
<td>Demonstrated Importance</td>
<td>$C_i$ is very strongly favored over $C_j$</td>
</tr>
<tr>
<td>9</td>
<td>Absolute Importance</td>
<td>The evidence favoring $C_i$ over $C_j$ is of the highest possible order of affirmation</td>
</tr>
<tr>
<td>2, 4, 6, 8</td>
<td>Intermediate</td>
<td>When compromise is needed, values between two adjacent judgments are used</td>
</tr>
</tbody>
</table>

Reciprocals of the above judgments: If $C_i$ has one of the above judgments assigned to it when compared with $C_j$, then $C_j$ has the reciprocal value when compared with $C_i$.

### Step2: Eigen Vector Calculation

Next, we have to evaluate the relative weights of the factors, which are relevant to the problem is called an eigen vector $\omega$.

$$A \ \omega = \lambda_{\text{max}} \ \omega, \ \lambda_{\text{max}} = n$$

(2)

Where, $\omega$ is eigen vector and $\lambda_{\text{max}}$ is eigen value. For a consistent matrix, $\lambda_{\text{max}} \geq n$.

### Step3: Consistency Index Calculation

Now, we have to evaluate Consistency Index (CI) for that matrix using

$$CI = \frac{(\lambda_{\text{max}}-n)}{n-1}$$

(3)

### Step4: Consistency Ratio

Finally, we have to evaluate consistency ratio (CR) using saaty average consistency index (RI) values as shown in Table4.

$$CR = \frac{CI}{RI}$$

(4)

Saaty also proposed that if the CR > 0.1, the judgements may not be consistent and unreliable. In such a case, a new comparison matrix is needed to set up until CR < 0.1. This way we can apply the AHP for predicting a decision based on available choices at hand.

### 4.2 Testability Study

In order to conduct testability study based on above model and AHP technique. The hierarchical model with factors – Encapsulation (F1), Inheritance (F2), Coupling (F3), cohesion (F4), Size & complexity (F5) and polymorphism (F6) has been shown below in fig2. In order to assign weights to these factors a survey form was being sent to 10 professional which are either academicians doing research in object oriented testing related subjects or having good knowledge of object oriented concepts or from industry professional practicing these methods. On basis of eigen value, eigen vector, consistency ratio and consistency index calculations, we have been able to evaluate weights for all these factors which is shown in detail in next section.

![AHP Hierarchy for Evaluation of Software Testability Based on Above Model](image-url)
5. Evaluation of Testability Model Using AHP

5.1 Proposed Model Evaluation

A square matrix of 6X6 is sent for pair-wise weight filling to 10 experts as discussed above. The mean matrix thus formed using these 10 samples on six testability factors is given below:

\[
\begin{bmatrix}
F1 & F2 & F3 & F4 & F5 & F6 \\
F1 & 1.00 & 1.35 & 4.50 & 3.20 & 0.55 & 1.55 \\
F2 & 1.23 & 1.60 & 4.30 & 3.30 & 1.07 & 1.40 \\
F3 & 0.23 & 0.24 & 1.00 & 0.63 & 0.22 & 0.26 \\
F4 & 0.32 & 0.31 & 1.95 & 1.00 & 0.27 & 0.31 \\
F5 & 1.55 & 1.60 & 4.70 & 3.80 & 1.00 & 1.40 \\
F6 & 0.95 & 1.10 & 3.90 & 3.30 & 1.10 & 1.00 \\
\end{bmatrix}
\]

There are many methods for calculating the eigenvector. We have used spreadsheet based approximate calculations for local priorities of criteria. The Eigen value thus calculated are as shown in table 5 below.

The eigenvector of the relative importance of \(F1, F2, F3, F4, F5\) and \(F6\) is \((0.22, 0.22, 0.04, 0.06, 0.25, 0.20)\), which is given in Table -5. These values are weights of main factors i.e. Encapsulation \((0.22)\), Inheritance \((0.22)\), Coupling \((0.04)\), Cohesion \((0.06)\), Size & Complexity \((0.25)\) and Polymorphism \((0.20)\) in testability assessment.

Now the six eigen values calculated for each of these factors is \((6.62, 6.61, 6.58, 6.47, 6.63, 6.60)\) with \(\lambda_{max}=6.59\) which is \(\geq 6\) (total no of factors), which is consistent. Using this we calculate the CI and CR values as follows:

\[
CI = \frac{(\lambda_{max}-n)}{n-1} = \frac{6.59-6}{6-1} = 0.12
\]

\[
CR = CI/RI = 0.12/1.24 = 0.09
\]

5.2 Testability Evaluate of Sample OO Projects:

We have applied the above testability assessment on three object oriented programs the data for which is taken from [46] which consists of three standard object oriented projects. Table 6 below shows the gathered metric value for each of the above mentioned programming features. Here the prime motivation is to show the applicability of the proposed scheme, irrespective of the size of the considered project. The AHP technique is applied on pair-wise comparison matrix of OO projects for each testability factor individually.

Table 6: Three Project Metrics Values[46]

<table>
<thead>
<tr>
<th></th>
<th>NOM</th>
<th>NOC</th>
<th>CBO</th>
<th>LCOM</th>
<th>WMC</th>
<th>NMO</th>
</tr>
</thead>
<tbody>
<tr>
<td>P1</td>
<td>6</td>
<td>3</td>
<td>1</td>
<td>0.5</td>
<td>6</td>
<td>1.5</td>
</tr>
<tr>
<td>P2</td>
<td>10</td>
<td>1</td>
<td>2.2</td>
<td>0.5</td>
<td>10</td>
<td>8</td>
</tr>
<tr>
<td>P3</td>
<td>8.8</td>
<td>1</td>
<td>2.2</td>
<td>1</td>
<td>8.8</td>
<td>1.5</td>
</tr>
</tbody>
</table>

The eigen vector value for all three projects with respect to six testability assessment factors-Encapsulation (Table7), Inheritance (Table8), Coupling (Table9), Cohesion (Table10), Size & Complexity (Table 11) and Polymorphism (Table12) are shown below. The solution with respective eigen vector values and respective CR \((0.07, 0.07, 0.07, 0.06, 0.07, 0.08)\) values are also below in these tables. All CR values are below 0.1. Hence, the judgements are consistent and acceptable.

This matrix eigen vector values are utilised in evaluating global utility of each project and its overall rank.

Table 7: Pair-wise Comparison Matrix of three OO Projects for Encapsulation

<table>
<thead>
<tr>
<th></th>
<th>P1</th>
<th>P2</th>
<th>P3</th>
</tr>
</thead>
<tbody>
<tr>
<td>P1</td>
<td>1.00</td>
<td>5.00</td>
<td>3.00</td>
</tr>
<tr>
<td>P2</td>
<td>0.20</td>
<td>1.00</td>
<td>0.25</td>
</tr>
<tr>
<td>P3</td>
<td>0.33</td>
<td>4.00</td>
<td>1.00</td>
</tr>
</tbody>
</table>

\(\lambda_{max}=3.09, CI=0.04, CR=0.07\)

Table 8: Pair-wise Comparison Matrix of three OO Projects for Inheritance

<table>
<thead>
<tr>
<th></th>
<th>P1</th>
<th>P2</th>
<th>P3</th>
</tr>
</thead>
<tbody>
<tr>
<td>P1</td>
<td>1.00</td>
<td>0.33</td>
<td>4.00</td>
</tr>
<tr>
<td>P2</td>
<td>3.00</td>
<td>1.00</td>
<td>5.00</td>
</tr>
<tr>
<td>P3</td>
<td>0.25</td>
<td>0.20</td>
<td>1.00</td>
</tr>
</tbody>
</table>

\(\lambda_{max}=3.09, CI=0.04, CR=0.07\)
Now finally we have to construct a matrix of the eigenvectors for three selected projects P1, P2 and P3 and six testability assessment factors weights F1, F2, F3, F4, F5, and F6 as mentioned below.

The overall global utility of each project is calculated using the summation of the products of the weight of OO Project with reference to each factor by the weights of corresponding factor yields the global utility of each OO Project.

\[
OOS \text{ Testability} = \frac{\sum_{i=1}^{n} Weight \ value \ of \ F_i * \ Comparative \ value \ of \ P_i}{Comparative \ value \ of \ P_i}
\]

For example: \(U(P1) = 0.22 \times 0.62 + 0.22 \times 0.28 + 0.04 \times 0.69 + 0.25 \times 0.62 + 0.2 \times 0.63 = 0.52\)

The best OO Project is the one which is having the highest overall testability index values. Accordingly, ranking of OO Project is done which are shown in Table 13 and P1 found to be the best choice as its testability index value is highest amongst three.

6. Result and Findings

The above technique has shown that role of encapsulation (22%), inheritance (22%), coupling (4%), Cohesion (6%), size& complexity (25%) and Polymorphism (20%) in overall testability assessment of any OO project as per sample survey based on AHP technique. The result here is utilised for three medium sized projects for overall testability index (TI) calculation. In actual situation, comparative values of characteristics can be gathered from running projects, which are developed using object oriented technology. Though, the projects, which are compared here, are medium size projects but still good enough to support the model. However, our motive is to show the applicability of proposed scheme for the testability estimation of object oriented software. Proposed schemes can be applied on real life software based on the values of identified six factors and it will determine the Testability Index (TI) for the considered software. It can be applied on each module (method, class, package, module etc) in order to know their testability or it can also be applied on whole developed system to know its overall testability.

7. Conclusion and Future Scope

In this paper we have proposed an object oriented testability model depending on internal object oriented software design features. The six OO factors affecting testability are – Encapsulation, Inheritance, Coupling, Cohesion, Size & Complexity and Polymorphism found and identified as per literature survey. We linked each of these features with suitable popular OO metrics only at design level. Now, in order to evaluate testability using above model we used analytical hierarchical process (AHP). The weights of each of these factors thus obtained using this technique was...
being applied on three medium sized projects for testability assessment.

In future the assessment of many core runtime testability factors and metrics may be analysed using AP technique along with large scale industrial survey. Later, this model can be cross validated using other techniques and help practitioners in testability estimation and improvisation first at design and later at source code level, which has not been covered in our study. Software practitioners can use the proposed approach for selecting the appropriate program in term of software testability for OO software.
